

Consider the problem of determining whether a Turing machine  $M$  on an input  $w$  ever attempts to move its head left when its head is on the left-most tape cell. This problem is formulated as a language:

$$L = \{ \langle M, w \rangle \mid M \text{ attempts to move its head left when its head is on the leftmost tape cell} \}$$

Assume that the language  $L$  is decidable and  $\hat{M}$  be a TM that decides the language  $L$ . Construct a TM,  $A$  that decides the halting problem.

$A =$  "on input  $\langle M, w \rangle$ :

1. Construct a TM,  $A'$ , from  $A$ . The TM  $A'$  moves  $w$  one tape cell to the right and marks the leftmost cell with #.
2. Run the TM  $A'$  on  $\langle M, w \rangle$ .
3. If  $A'$  encounters # then  $A'$  moves to the right side and simulates  $M$  reaching the leftmost tape cell.
4. If  $M$  halts and accepts on  $w$  then  $A'$  simulates to move its head left when its head is on the leftmost tape cell."

Now, TM  $A$  runs  $\hat{M}$  on the input  $\langle A, w \rangle$ . If  $\hat{M}$  accepts,  $A$  accepts. Otherwise,  $A$  rejects. It is assumed that  $\hat{M}$  be a TM that decides the language  $L$ . If  $M$  halts and accepts on  $w$ , then only  $A'$  moves its head left when its head is on the left-most tape cell. If  $A$  decides the halting problem, then halting problem is decidable. Thus, the halting problem is undecidable. It is a contradiction.

Therefore, the language  $L$  is undecidable.
